METROPOLITAN INFRASTRUCTURE INITIATIVE SERIES AND METROPOLITAN OPPORTUNITY SERIES

# Transit Access and Zero-Vehicle Households

Adie Tomer

"Zero-vehicle
households live in
neighborhoods wellserved by bus and rail
service ... However,
that transit service
frequently falls
short on connecting
households to ample
job opportunities."

### **Findings**

An analysis of data from the American Community Survey and 371 transit providers in the nation's 100 largest metropolitan areas reveals that:

- In the nation's largest metropolitan areas, 7.5 million households do not have access to a private automobile. A majority of these zero-vehicle households live in cities and earn lower incomes. Conversely, households with vehicles tend to live in suburbs and earn middle or higher incomes. The unique locational and income characteristics of zero-vehicle households reinforce their need for strong transit service.
- Over 90 percent of zero-vehicle households in large metropolitan areas live in neighborhoods with access to transit service of some kind. This greatly exceeds the 68 percent coverage rate for households with a vehicle, suggesting transit service aligns with households who rely on it most. However, some 700,000 zero-vehicle households in the 100 largest metro areas lack access to transit.
- The typical metropolitan household without a vehicle can reach over 40 percent of metro-wide jobs via transit within 90 minutes, exceeding the 29 percent transit access share for households with a vehicle. The tendency of zero-vehicle households to live in cities contributes to their above-average access to jobs via transit. Unfortunately, limited job access via transit in most metropolitan areas leaves many jobs out of reach for zero-vehicle households.

Millions of zero-vehicle households live in areas well served by transit. Yet hundreds of thousands of zero-vehicle households live out of transit's reach, particularly in the South and in the suburbs. And those with transit access still cannot reach a majority of jobs in metro areas within 90 minutes. Based on these trends, leaders must recognize these households' unique mobility needs and aim to improve job accessibility through sound policy.

### Introduction

mericans possess a well-documented dependency on the automobile—and nowhere is that clearer than in how Americans travel to work. Over three-quarters of commuters drive alone to work, with another 10 percent carpooling.¹ Considering that Americans registered over 133 million private and commercial vehicles in 2009, it makes sense that so many people would drive.² However, there remain over 10 million American households who do not own a private vehicle.³

Not only do these households live without access to a personal vehicle, but these zero-vehicle households also must commute in an employment environment particularly unsuited to their travel options.<sup>4</sup> The United States added over 655,000 roadway lane miles since 1980, leading to the rapid decentralization of housing and jobs.<sup>5</sup> Such decentralization leaves a zero-vehicle

household's most likely travel modes—transit, walking, and biking—at a structural disadvantage due to evergrowing distances between locations.<sup>6</sup>

For some, not owning a vehicle represents a lifestyle choice. Such individuals may live in locations where car ownership is particularly expensive or impractical, and there are plentiful transportation alternatives for accessing jobs and meeting other household needs. As explained below, however, census data imply that the majority of these zero-vehicle households face economic constraints to automobile ownership. Not only are cars themselves expensive, but households with lower incomes may also face higher costs for financing a car. Used cars offer a cheaper sticker price but tend to incur higher annual operating costs.<sup>7</sup> Not owning a car may impart further economic disadvantage as well, as workers with cars work more hours per week than those without cars, enabling them to earn higher incomes.<sup>8</sup>

Based on these environmental and economic disadvantages, public policy has a responsibility to improve transportation accessibility for zero-vehicle households. First, it should ensure that people who are most constrained in their transportation choices—low-income zero-vehicle households—have access to viable transportation options. Second, it should expand transportation options for all households, including those who can afford a car but choose not to, because of the attendant environmental and economic benefits.

To meet these responsibilities, policymakers need a strong understanding of zero-vehicle households' geographic distribution and demographic characteristics. That understanding should inform the response of metropolitan transit systems to these households' transportation needs. Brookings' "Missed Opportunity" report found that large metropolitan areas face a transit paradox. Transit agencies offer at least basic fixed-route transit service to a majority of their working-age population, but those same services fall short on connecting workers to jobs. Do zero-vehicle households face this same paradox?

This brief begins by profiling zero-vehicle households: who they are, what they earn, and where they live. Next, using a comprehensive "supply side" transportation model, the brief examines how many zero-vehicle households have an opportunity to use transit and if that service helps them reach metropolitan job opportunities. It concludes with a discussion of the implications for public policy.

### Methodology

This brief combines detailed data on household demographics, transit systems, and employment to determine the accessibility of jobs via transit within and across the country's 100 largest metropolitan areas—as defined by the U.S. Office of Management and Budget in 2008 and based on Census Bureau population estimates for that year.

Besides the demographic analysis in Finding A—which primarily uses American Community Survey data—this brief utilizes the same data sources and nearly all of the same methodological specifications as Brookings' "Missed Opportunity" report. To get a complete understanding of that report's methodology, please read that report's Appendix 1 (PDF). The exceptions to those specifications are:

**Origin Unit:** While Missed Opportunity measured neighborhoods by the number of residents aged 18 to 64, this brief measures neighborhoods by the number of households with and without a vehicle. This switch from population to household statistics means that each report's results are not comparable to one another.

**Exclusion of Combined Access:** This brief does not include a combination of the coverage and job access statistics, instead focusing on individual rankings within the two statistics.

Finally, a note about the transit agencies included in this analysis. The model requires specific service times to measure access between origins and destinations—meaning only fixed route transit meets this criterion. In turn, this requirement excludes alternative transit, such as on-demand service and private jitneys, from the analysis. Innovative carpooling programs, like slugging, are also excluded. There is no question that these travel modes offer a viable alternative to fixed route transit and private automobiles—and statistics show that people do use the services. Future analyses could measure the additional accessibility benefits these services offer to zero-vehicle households.

### **Findings**

A. In the nation's largest metropolitan areas 7.5 million households do not have access to a private automobile.

Households without access to a personal vehicle, referred to here as zero-vehicle households, are a clear minority across the country's 100 largest metropolitan areas—but still form a large group. They make up 10 percent of all households in those large metropolitan areas, equaling 7.5 million households.<sup>10</sup>

The majority of these zero-vehicle households live in just a handful of metropolitan areas. New York is the clear leader with 28.0 percent of the 100 metropolitan areas' zero-vehicle households. The next largest share belongs to Chicago, followed by Los Angeles, Philadelphia, and Boston. Overall, just seven metropolitan areas host over half of all 100 metro areas' zero-vehicle households (Table 1).

Table 1. Zero-Vehicle Households, by Metropolitan Area, 2010 Zero-Vehicle 100 Metropolitan Metropolitan Area Households Area Share New York-Northern New Jersey-Long Island, NY-NJ-PA 2,093,861 28.0% Chicago-Naperville-Joliet, IL-IN-WI 399,927 5.3% Los Angeles-Long Beach-Santa Ana, CA 358,705 4.8% Philadelphia-Camden-Wilmington, PA-NJ-DE-MD 310,583 4.1% Boston-Cambridge-Quincy, MA-NH 223,207 3.0% 195,997 San Francisco-Oakland-Fremont, CA 2.6% Washington-Arlington-Alexandria, DC-VA-MD-WV 193,558 2.6% **Total of Other 93 Metro Areas** 3,714,076 49.6% 39,936 Average of Other 93 Metro Areas 0.5% Source: Brookings Institution analysis of Nielsen Pop-Facts 2010 data

Whether in New York or Provo, the metro with the smallest share of zero-vehicle households, the 7.5 million zero-vehicle households differ in several respects from households with access to a personal vehicle.

First, a majority of zero-vehicle households live in cities: 61.7 percent of all zero-vehicle households live in the 132 primary cities of the 100 largest metropolitan areas. 11 This is more than double the 28.5 percent city-living share of households with a vehicle. Confirmed in the "Missed Opportunity" report, these city locations help put zero-vehicle households in the optimal place to use transit's hub-and-spoke designs.

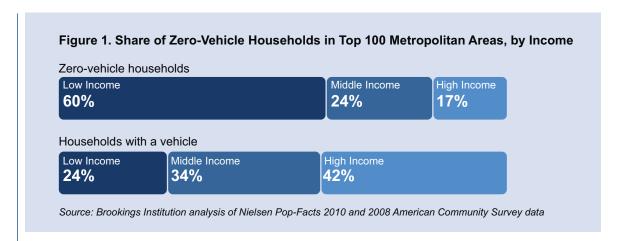

These metro areas' commuting statistics reinforce this locational advantage—59.7 percent of zero-vehicle households in the city use mass transportation as their commuting mode. This dwarfs the 25.4 percent transit share for zero-vehicle households in the suburbs. This implies that three-quarters of zero-vehicle households in the suburbs need an alternative mode to get to work. Invariably these households borrow someone else's car and drive alone (31.1 percent share) or carpool with someone else (30.2 percent share).

Second, a similar majority of zero-vehicle households have lower incomes. Throughout the 100 metropolitan areas, 59.8 percent of zero-vehicle households have incomes below 80 percent of the median income for their metro area. The share is essentially the same across cities (59.8 percent) and suburbs (59.7 percent). By comparison, only 23.9 percent of households with a vehicle are low income.

These household income shares are consistent across nearly all metropolitan areas. In only three of the 100 metro areas do less than half of zero-vehicle households fall into the low-income category: New York, Lakeland, and Oxnard.

While large shares of zero-vehicle households live in cities and earn low incomes, racial profiles are relatively consistent across the three largest racial categories. Whites constitute the highest share of all

zero-vehicle households (36.4 percent), but Hispanics (27.7 percent) and blacks (25.3 percent) are not far behind. Zero-vehicle households truly stretch across all racial lines.

## B. Over 90 percent of zero-vehicle households in large metropolitan areas live in neighborhoods with access to transit service of some kind.

Across the country's 100 largest metropolitan areas, zero-vehicle households tend to congregate in cities and earn relatively low incomes. This puts them in a unique position to take advantage of mass transit, on account of both density and transit route configurations. This finding examines transit coverage, or the share of a metro area's households living in communities served by transit.

Over 90 percent of zero-vehicle households live in neighborhoods with transit coverage. This suggests that zero-vehicle households do align their settlement locations with transit provision, and that transit agencies align their routes to serve these households.<sup>12</sup>

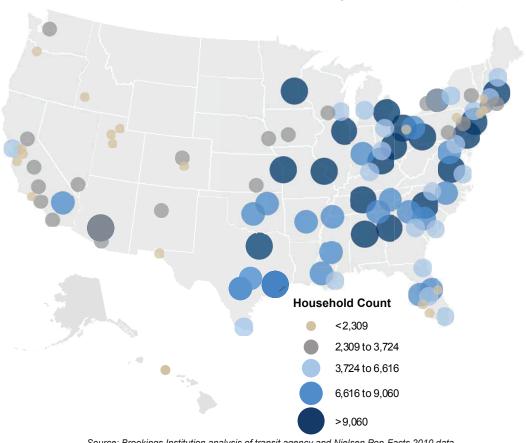

A major reason the zero-vehicle coverage rate exceeds 90 percent is that some of the metro areas with the highest share of zero-vehicle households also have the highest coverage rates. New York is the best example: It houses over one-quarter of all zero-vehicle households in the 100 largest metro areas, and 98.7 percent of those households live in neighborhoods with transit service. Another seven metro areas are home to at least 2 percent of all 100 metro areas' zero-vehicle households, and at least 90 percent of their zero-vehicle households live in transit-covered neighborhoods.

In contrast, certain metropolitan areas have startlingly low coverage rates for their zero-vehicle households. Greenville is the only metro area in which more than half of zero-vehicle households live in neighborhoods without transit coverage. Another eight metro areas fall below 60 percent coverage for zero-vehicle households. The only silver lining is that most of the nine worst metropolitan performers have small zero-vehicle household populations, minimizing their impact on overall metropolitan access (Map 1).

However, some metro areas with subpar coverage of zero-vehicle households leave large numbers unserved. Atlanta, Dallas, and Houston all offer lower transit coverage rates and each house over 1 percent of all 100-metro zero-vehicle households. Together those three metro areas leave over 100,000 zero-vehicle households without access to transit. Across all 100 metro areas, 700,000 households lack access to both private vehicles and transit in their neighborhoods.

Regional statistics reinforce the disparities between strong and weak metropolitan performers, although the variation is more muted. The coverage rate for zero-vehicle households is highest in Northeastern metro areas, (96.2 percent), followed closely by those in the West (94.8 percent) and Midwest (87.1 percent). Even Southern metros (79.7 percent) perform well relative to transit coverage for households with vehicles (Table 2).

Coverage rates for zero-vehicle households are even higher in cities. Across the 100 largest metro areas, 99.2 percent of zero-vehicle households in cities live near transit, versus only 58.0 percent in the suburbs. Transit coverage rates for zero-vehicle households exceeded 90 percent in 95 of the 100 largest metro

areas' cities; the lowest was 74 percent in Cape Coral, FL. Conversely, in only 16 metro areas did at least 90 percent of suburban zero-vehicle households live in neighborhoods with coverage. In 31 metro areas, more than half of suburban zero-vehicle households live in neighborhoods without coverage, affecting a total of 263,000 households without vehicles.

Notwithstanding relatively low transit coverage for zero-vehicle households in some metro areas, most areas do much better on behalf of those mobility-constrained households than they do for the population at large. In Richmond, 68.4 percent of zero-vehicle households enjoy transit coverage, versus 31.2 percent of households with a vehicle. In another six metro areas, at least 30 percentage points separate coverage rates between the two household groups: Portland ME, Poughkeepsie, Indianapolis, Chattanooga, Atlanta,

and Birmingham. All seven offer sub-50 percent coverage for their households with a vehicle, suggesting that they are optimizing service provision for households who may need transit the most. Large coverage differences also characterize the suburbs of Baltimore, Boston, Philadelphia, and Chicago, in which strong commuter rail and bus systems help make suburban living possible without a car.

# C. The typical metropolitan household without a vehicle can reach over 40 percent of metro-wide jobs via transit within 90 minutes, exceeding the 29 percent transit access share for households with a vehicle.

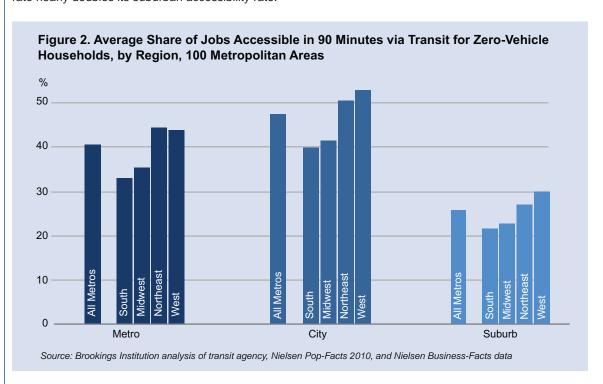

Beyond offering basic service, one of transit's principal functions is to get commuters to work. This section measures transit's ability to perform that accessibility function within an allotted time threshold.

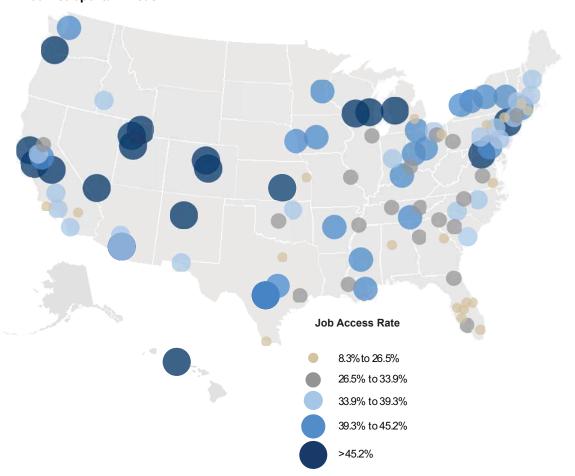

Across all neighborhoods served by some form of transit in the 100 largest metro areas, the typical zero-vehicle household can reach 40.6 percent of metropolitan jobs within 90 minutes of travel time.

While 40.6 percent of jobs may not sound like an especially large share, it easily exceeds the 28.6 percent of jobs reached by the typical household with a vehicle. A major reason for this difference is the concentration of zero-vehicle households in cities: 61.7 percent of all zero-vehicle households live in cities, nearly double the rate for households with a vehicle. City-based households stand to benefit from the hub-and-spoke design found in most metropolitan transit systems, where transit lines converge in downtowns and offer these households access to multiple metropolitan destinations. Cities' higher densities also enable access to more jobs within shorter distances.

Accessibility statistics within metro areas reinforce the importance of zero-vehicle households' location for job access. Zero-vehicle households in cities can reach on average 47.4 percent of metropolitan jobs, exceeding the 25.8 percent average for their suburban counterparts. These rates exceed those for households with a vehicle, both in the city (39.3 percent) and in the suburbs (21.4 percent).

Much like coverage statistics, job access varies across the four regions. Northeastern metro areas lead the way with 44.4 percent access for zero-vehicle households, followed by Western (43.7 percent) and Midwestern (35.4 percent) metro areas. Southern metros (33.1 percent) continue to perform worst across both coverage and job access for these households. Figure 2 also shows that each region's city accessibility rate nearly doubles its suburban accessibility rate.

Map 2. Share of Jobs Accessible on Average in 90 Minutes via Transit, Zero-Vehicle Households in 100 Metropolitan Areas

Source: Brookings Institution analysis of transit agency, Nielsen Pop-Facts 2010, and Nielsen Business-Facts data

Several Western metro areas stand out in providing high job access via transit for zero-vehicle households. Honolulu is the best performer out of all 100 metro areas—and the only metro to break 70 percent average job access—followed by Salt Lake City, Tucson, and San Jose. In all, 13 of the 20 best job access levels for zero-vehicle households belong to Western metros. Some of the country's largest metropolitan areas are also top performers. New York, Washington, and San Francisco all rank among the top 20. And since these three metro areas house 33 percent of all zero-vehicle households, they also positively influence the aggregate 100-metro performance.

At the other end of the spectrum, Southern metros dominate the list of lowest job access levels. Eleven (11) of the 20 worst performing metros are in the South, including six of the eight largest Florida metros. Some of the country's largest metropolitan areas outside the South also register lower job access levels: Detroit, Riverside, and Kansas City all rank among the bottom 20. Especially troubling are large metros like Dallas and Houston that underperform in both transit coverage and job access for zero-vehicle households.

Finally, how a metro area performs on job access for zero-vehicle households generally reflects how it performs on job access for households with vehicles. Nine metro areas rank in the top 10 on job access via transit for both zero-vehicle households and households with vehicles, while the 10 bottom-ranked metro areas are the same for both groups. In addition, in only seven metropolitan areas does the job access rank change by at least 20 spots between zero-vehicle households and households with vehicles.

#### Conclusion

his analysis reinforces the transit paradox first uncovered in the "Missed Opportunity" report. Zerovehicle households live in neighborhoods well-served by bus and rail service, and transit agencies align their routes to serve neighborhoods with zero-vehicle households. However, that transit service frequently falls short on connecting households to ample job opportunities, even though job access is better for zero-vehicle households than other households. And while transit reaches the majority of these mobility-constrained households, it still leaves 700,000 without access to transit. These households without coverage are then forced to either borrow a car or carpool to reach jobs too far to reach by foot or bike.

Beyond accessibility, the characteristics of zero-vehicle households are remarkably similar across selected demographic categories. Over 60 percent of zero-vehicle households live in cities, and a similar share qualify as low income. In particular, these low-income households may have difficulties purchasing and maintaining their own automobiles, making transportation alternatives that much more important.

These findings mean that policymakers must pay special attention to zero-vehicle households' transportation accessibility. Transit agencies should continue to address the coverage gaps in their systems, whether through fixed routes or alternatives like demand-response services. Simultaneously, routes should reflect job growth in the suburbs and assist households in reaching these opportunities. But transit agencies cannot alone tackle the needs of these households. Land-use planners should begin to concentrate future development in locations accessible from core cities.

Finally, these findings should serve as a wake-up call for those metropolitan areas with the troublesome combination of large-scale housing and job decentralization, large swaths of uncovered neighborhoods, and low levels of job access for zero-vehicle households. This group includes some of the largest metropolitan areas like Dallas and Atlanta, but also smaller metropolitan areas like Birmingham and Greenville. These metro areas will require a significant change in direction to enable households who need transit most—whether in cities or suburbs—to connect to opportunities throughout their region.

- The definition of a zero-vehicle household is from the American Community Survey 2008 Subject Definitions (PDF): "The data on vehicles available were obtained from Housing Question 9 in the 2008 American Community Survey. The question was asked at occupied housing units. These data show the number of passenger cars, vans, and pickup or panel trucks of oneton capacity or less kept at home and available for the use of household members. Vehicles rented or leased for one month or more. company vehicles, and police and government vehicles are included if kept at home and used for non-business purposes. Dismantled or immobile vehicles are excluded. Vehicles kept at home but used only for business purposes also are excluded.

- 12. Previous research finds that low-income people may also move to neighborhoods served by transit at higher rates than other groups, especially since so many zero-vehicle households are also low income. Edward L. Glaeser, Matthew E. Kahn, and Jordan Rappaport, "Why Do the Poor Live in Cities?" (Cambridge, MA: Harvard Institute of Economic Research, Harvard University, April 2000).

### Acknowledgments

This paper is the second in a series based on a multi-year transportation accessibility project. First, we want to thank project co-leads and chief editors on this paper: Alan Berube and Elizabeth Kneebone. We also want to thank the other Brookings Institution collaborators: Rahsheeda Ali, David Jackson, Christopher Ingraham, and Louis Liss. The entire project team is also grateful to colleagues at Brookings and experts in the field who contributed to the underlying model and the original "Missed Opportunity" report.

The Metropolitan Policy Program at Brookings thanks the Surdna Foundation and the Rockefeller Foundation for their support of the program's Metropolitan Infrastructure Initiative, and the Ford Foundation for its generous support of the program's research on city and suburban poverty. The John D. and Catherine T. MacArthur Foundation, the Heinz Endowments, the George Gund Foundation, and the F.B. Heron Foundation provide general support for the program's research and policy efforts.

### **For General Information**

Metropolitan Policy Program at Brookings 202.797.6139 www.brookings.edu/metro

The Brookings Institution is a private non-profit organization. Its mission is to conduct high-quality, independent research and, based on that research, to provide innovative, practical recommendations for policymakers and the public. The conclusions and recommendations of any Brookings publication are solely those of its author(s), and do not reflect the views of the Institution, its management, or its other scholars.

Brookings recognizes that the value it provides to any supporter is in its absolute commitment to quality, independence and impact. Activities supported by its donors reflect this commitment and the analysis and recommendations are not determined by any donation.

# **About the Metropolitan Policy Program at Brookings**

Created in 1996, the Metropolitan Policy Program provides decisionmakers with cutting-edge research and policy ideas for improving the health and prosperity of metropolitan areas including their component cities, suburbs, and rural areas. To learn more, visit www.brookings.edu/metro

# **About the Brookings Metropolitan Infrastructure Initiative**

Launched in 2008, the goal of the Metropolitan Infrastructure Initiative is to develop timely, independent analysis, frame key debates, and offer policy recommendations to help leaders in the United States and abroad address key infrastructure challenges with specific emphasis on transportation. This and other publications, speeches, presentations and commentary on transportation and infrastructure are available at: www.brookings.edu/metro/Infrastructure-Initiative.aspx

# **About the Brookings Metropolitan Opportunity Series**

Launched in 2009 the Metropolitan Opportunity Series documents the changing geography of poverty and opportunity in metropolitan America, analyzes its drivers and implications, and offers policy recommendations to enhance the well-being of lower-income families and communities in both cities and suburbs. This study and other publications, speeches, presentations and commentary in the series available at: www.brookings.edu/metro/Metropolitan-Opportunity.aspx
