- Size of the Benefit
- Methodology and Data
- Results
- **Concluding Remarks**

- We are interested in the following;
- $\Box$  It is obvious there is direct tax benefit.
- □ However, there might also be some positive spillover effects (gentrification).
- More general, is the law simply a tax pass-trough to existing landowners, or is there actually some value creation?
- We analyze **prices** and **liquidity** of commercial real estate.
  - □ Any expected future rent growth, should be priced in now.
  - We argue that young properties cannot enjoy the tax breaks, thus any effect measured here, must come from the fact that positive gentrification effects are expected.
  - We also analyze older properties and vacant land sales. We compare any possible price increases here and compare it with the total maximum tax break possible. (A bit back-of-the-envelope.)

**Concluding Remarks** 

Consider the following two Eqs;

no OZ: 
$$I_0 = \sum_{t=1}^{T} \frac{CF_t}{(1+c)^t} + \frac{TV}{(1+c)^T} - I_0 x - \frac{(TV - I_0)x}{(1+c)^T}$$
  
OZ:  $I_0 = \sum_{t=1}^{T} \frac{CF_t}{(1+c)^t} + \frac{TV}{(1+c)^T} - \frac{(1-0.15)I_0x}{(1+c)^{t_i}}$ 

where we assume;

 $\Box \quad TV = I_0 \times (1+g)^T.$ 

□ The initial investment is funded entirely from (past) capital gains.

□ Cash flow and discount rates are **after-tax**.

We can compute the difference between the two;

$$\Delta OZ = x \left( 1 - \frac{0.85}{(1+c)^{t_i}} + \frac{(1+g)^T - 1}{(1+c)^T} \right).$$

```
Results
```

- Many census tracts were chosen by the federal government to be potential OZ. Out all these eligible census tracts, the individual states designated about 25% of these.
- In essence we perform a Difference-in-Differences (DiD) setup exploiting this designation process.
  - First we perform Propensity Score Matching (PSM) to closely match 1 on 1 designated census tracts with eligible (but not designated) census tracts, based on poverty and income levels.
  - We only look at a relative tight band around the treatment (which happened early 2018), to alleviate any non-parallel trend issues (2017 2019). We also look within counties.
  - □ We run a OLS (for pricing) and Logit (for liquidity) which includes a treatment dummy.
  - □ Given that we believe age might have an effect, we also break the sample in age cohort and do rolling regressions.
  - □ Finally, we also look at how persistent/consistent the designation effect has been.

- CAPEX
- Results
- Concluding Remarks

- For this research we use data provided to us by Real Capital Analytics (RCA).
- RCA is the premier transaction data provider world-wide.
- According to their numbers, they "catch" 95% of all transactions in the US.
- The property needed to have been sold for at least \$2.5M in its history once. (So no mom and pop stores.)
- We got the full dataset, meaning 100% of their transaction prices, plus a full set of characteristics, like size, age, property type, location, etc.
- After only looking at the OZ properties + control group between 2017 and 2019, we end up with <u>12,111 observations</u> for the **existing properties**, and 1,129 observations of **vacant land** transactions.

Other Models

- We also estimated a couple of other ("robustness") models;
  - □ **Breaking up by property type.** We find the biggest effects in office and apartment.
  - □ **Breaking up by major metros vs non-major metros.** The biggest effect is in the non-major metros, but still large in the major metros.
  - □ **By size of the real estate.** Most of the price effect in the smaller properties, but liquidity increase mostly for large properties.
  - Directly measure spillover effects. We find no spillover effects.

Methodology and Data

Results

Concluding Remarks

How Large is The Effect?

# How Large is The Effect?

and a state of the

- For the existing older properties;
  - Assuming investors put exactly the same amount of capital expenditures in the property, the total maximum benefit is approximately 32%.
  - $\Box$  The largest price effect we find is 21%.
- For the vacant land;
  - Assuming the average Land Value Fraction (LVF) is 20% for commercial real estate in the US, we find the maximum theoretical benefit is 80%.
  - $\Box$  Our largest estimate is 53%.
- For new properties (needed to find the indirect effect) we do not find a price increase, however we do see that liquidity is up in (late) 2019.
